

Sensitivity checks support keeping one common 70% latency rule

Five paper-benchmark regions were recomputed under stricter gating, raw-bin timing, and alternative thresholds.

A Which analysis choices move the latency?

Green squares: gate ON—every original crossing was already significant, so all remain at 0 ms.
Orange circles: no interpolation—0–8 ms later; total paper discrepancy 59 → 43 ms with interpolation.

B Can one new threshold match the paper?

Each dot is the threshold that best reproduces that region's paper latency; one global replacement should cluster.

Decision → keep the prespecified 70% rule

The significance gate is neutral; interpolation reduces binning error; region-specific retuning would be cherry-picking.
